

Ecological Applications of Wireless Sensor Networks

Brian Neiswander

Faye Walker

Professor Tom Little

Multimedia Communications Lab

Boston University Summer 2006 Photonics REU: Final Report

This Presentation

- Project Goals
- Wireless Sensor Networks
- Motes
 - Attenuation
 - Calibration
- Field Tests
- Photosynthesis
- Future Work

Project Goals

- Measure ecological data with wireless sensor networks
 - Software
 - Hardware
 - Data Collection
- Show that wireless sensor networks are better than conventional methods for evaluating photosynthesis

Wireless Sensor Networks

- Use small, self-contained sensors called motes
- Data sent with radio, laser, infrared
- Ad hoc network
 - Each mote becomes aware of nearby motes and form a network
 - Self forming

Hop Scenarios

Single-Hop

data is sent directly from a mote to the base station (limited range)

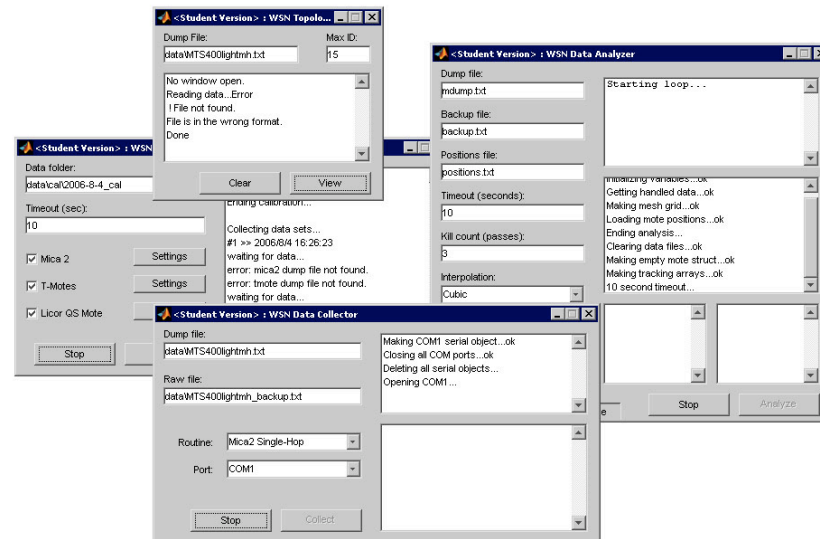

Multi-Hop

data is passed from a mote to other motes and then to the base station (long range)

Collection and Analysis

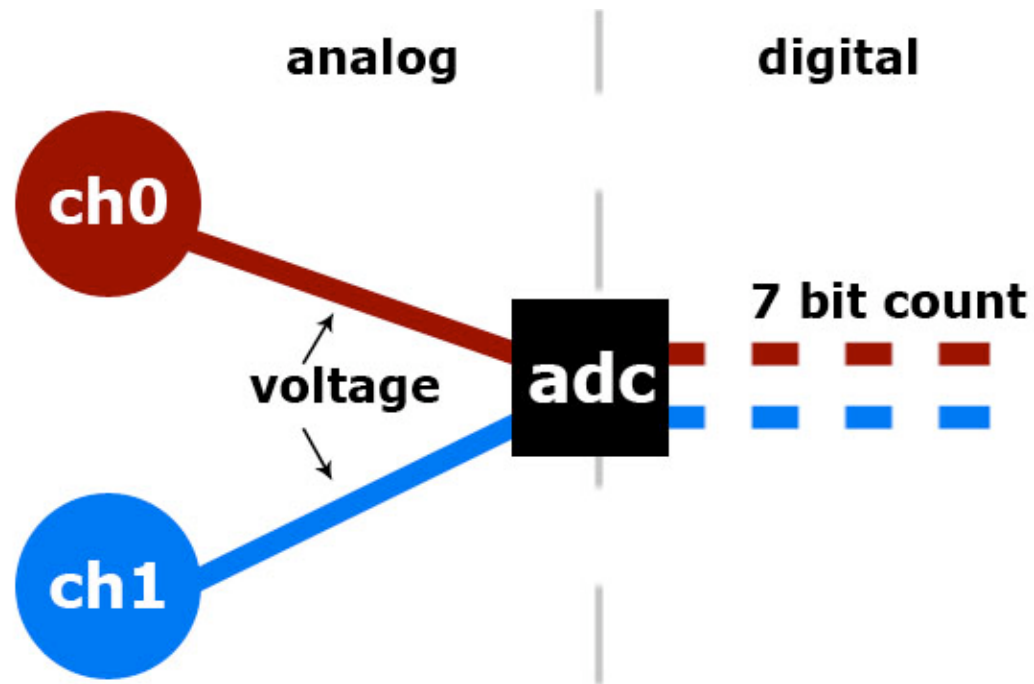

- MATLAB applications package
 - Data collectors
 - Calibrator
 - Real-time and post analyzers
 - Engineering unit converters

Our Motes

	Mica2	Tmote Sky
Light Intensity	X	X
Temperature	X	X
Humidity	X	X
Pressure	X	
Acceleration	X	
Low Power Mode	X	X
Our Uses:	Large scale light collection	Bat barn animal study

Light Sensor

- Two 7-bit counts
 - If ch0 or ch1 count > 1111111
 - Overflow
 - Sensor saturates

Sensor Attenuation

- Sensor filters
 - 1000x wratten
 - ~5x paper

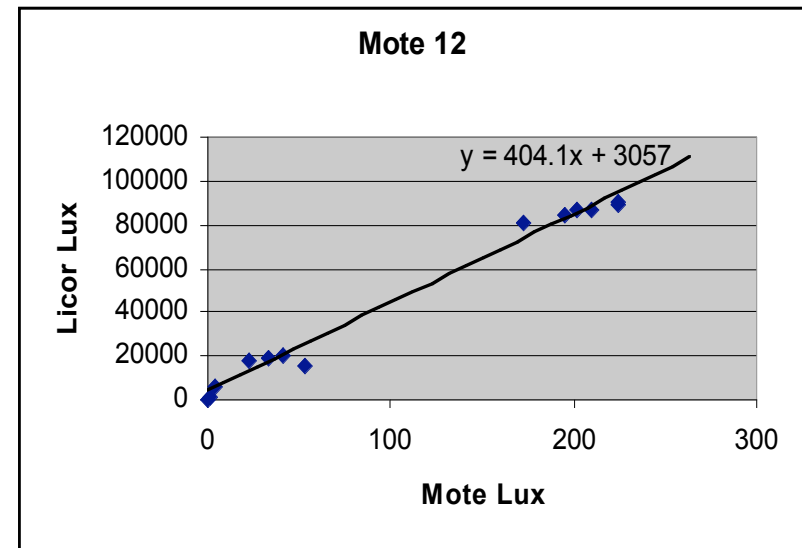

Calibration

- Heavy attenuation requires calibration
- Difficult to calibrate for large range of light
 - 12 hour test (sunrise to sunset)
- Calibrate each mote against a very accurate control light sensor
 - ADC mote

Calibration Solution

- Voltmeter to measure control sensor
- Log data by hand
- Linear calibration equation for each mote

Open Field Test

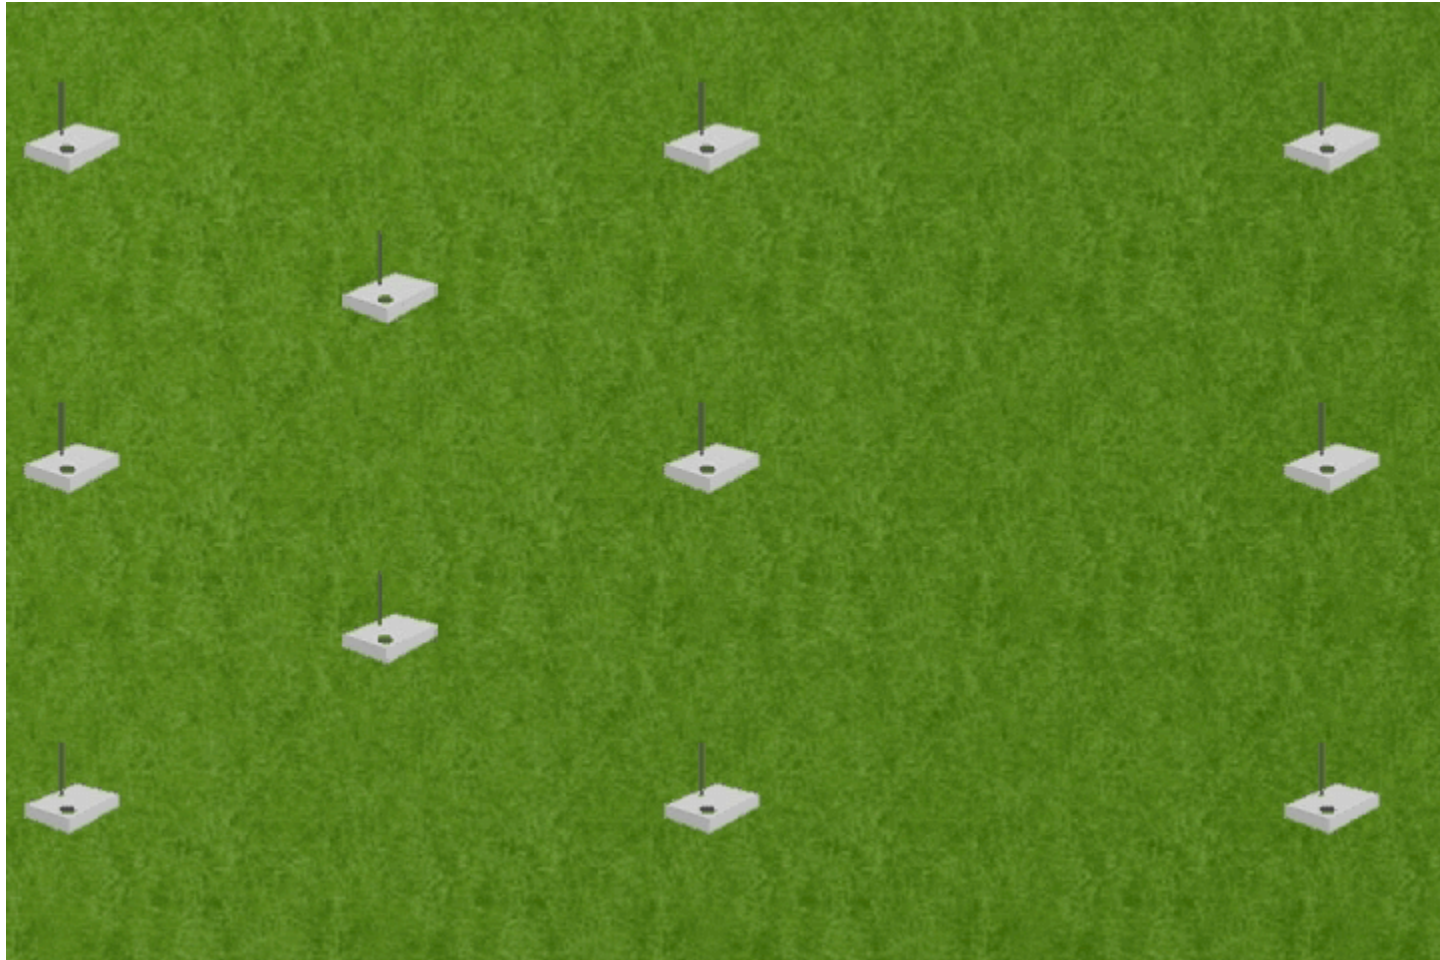

- 11 Mica2 motes
 - Record light intensity
 - Multi-hop scheme

- Video
 - Mote layout
 - Animated plots
 - Contour plot
 - Surfaced plot

Video

Static Photosynthesis Models

- Light intensity is only independent variable
- Input parameters dependent upon species

Non-rectangular (Peri et al.):

$$P(h) = \frac{P_{\max} + \alpha h - \sqrt{(P_{\max} + \alpha h)^2 - 4\theta\alpha P_{\max}}}{2\theta}$$

Rectangular $\theta = 0$ (Sullivan et al.):

$$P(h) = \frac{\alpha h P_{\max}}{\alpha h + P_{\max}}$$

h - light

P_{\max} - maximum photosynthetic rate at saturation

α - initial slope of the light-response curve

θ - curvature indicator

Dynamic Photosynthesis Model

- Dynamic equation varies with time

$$P(t, h) = P_{t-1} + (P_t - P_{t-1})e^{-t\tau}$$

- Accounts for increases and decreases in light
- Utilizes predicted steady-state values from the previous models
- (Naumburg et al.)

The image is a pixelated landscape. The top portion is a clear blue sky, transitioning into a hazy, light-colored horizon. Below the horizon, the terrain is depicted with various shades of brown, tan, and orange, suggesting a field or forest. The bottom portion of the image is a dark, solid green, representing a dense forest or a field of tall grass. The overall style is low-resolution and pixelated.

Conventional Photosynthesis Analysis

WSN Photosynthesis Analysis

Future Work

- Bat barn field test
 - Collect environmental data (light, temp, hum.)
- Get better calibrations
- Apply photosynthesis equations to light data
- Simulate conventional methods with WSN light data
 - Evaluate WSN effectiveness

Summary

- Wireless sensor networks collect data easily and efficiently at high resolutions
 - Useful in ecological studies
- Sensors must be adjusted to suit the testing environment
 - Attenuation
 - Calibration
- Field tests don't always go as planned
 - Murphy's law
- Photosynthesis equations should be better behaved with WSN data

We would like to thank the NSF,
Boston University, and Professor Tom Little
for this great research opportunity.

Any Questions?
